

Introduction

When substances are brought in contact with each other, they intermingle with each other. This phenomenon is known as diffusion. Diffusion takes place very rapidly in case of gases, to a lesser extent in case of liquids, and not at all in the case of solids.

However, diffusion of solids in liquids does take place, albeit at a very slow rate.

If a solid is kept in contact with excess of solvent in which it is soluble, some portion of the solid gets dissolved. This process is known as dissolution of a solid in liquid, and it takes place due to the diffusion of solid particles into liquid medium.

Molecules of solute are in constant random motion due to the collision between molecules of solute and that of the solvent. It is this physical interaction between solute-solvent particles that leads to diffusion.

Objective

To demonstrate that rate of diffusion depends upon the following factors:-

Temperature: As temperature increases, the kinetic energy of the particles increases. Thus, the speed of particles also increases, which in turn increases the rate of diffusion.

Size of the particle: As the size of particle increases, rate of diffusion decreases. This is because the particles become less mobile in the solvent.

Mass of the particle: As the mass of the particle increases, the rate of diffusion decreases; as the particle becomes less mobile.

Experiment 1

To study diffusion when copper sulphate is brought in contact with water (liquid).

Requirements

Copper sulphate (CuSO_4) crystals, 100 ml beaker

Procedure

1. Take about two grams of copper sulphate crystals in 100 ml beaker.
2. Add about 50 ml of water and allow it to stand for few minutes.
3. Note the development of blue colour in water.
4. Allow to stand further till it is observed that all copper sulphate disappears.
5. Note the blue colour change in water.

Conclusion

When solids such as copper sulphate are brought in contact with liquids such as water, intermingling of substances, i.e., diffusion takes place.

Experiment 2

To study the effect of temperature on the rate of diffusion of solids in liquids.

Requirements

Copper sulphate (CuSO_4) crystals, three 100 mL beakers, watch glass, wire gauge, burner, tripod stand, thermometer, stop watch.

Procedure

1. Take five gram of copper sulphate each in three beakers.
2. Pour 100 mL of distilled water slowly in one of the beakers.
3. Cover this beaker with a watch glass.
4. Pour 100 mL of cold water in a second beaker slowly.

5. Place a third beaker containing 100 mL of water on a tripod stand for heating.
6. Observe the diffusion process which begins in all the beakers.
7. Record of copper sulphate the time taken for the dissolution of copper sulphate in all the three cases.

OBSERVATION

Conclusion

The rate of diffusion of copper sulphate in water is in the order as given below:

Beaker 3 > Beaker 2 > Beaker 1

Thus, the rate of diffusion varies directly with temperature.

Experiment 3

To study the effect of size of particles on the rate of diffusion of solids in liquids.

Requirements

Graduated 100 mL measuring cylinders, copper sulphate (CuSO_4) crystals of different sizes, stop watch.

Procedure

1. Add 50 mL of water to each of the three cylinders.
2. Take five gram each of big size, medium size,
 1. Crystals of copper sulphate, and add them separately cylinders.
 2. Allow to them to stand for sometime.
 3. Note the time taken for blue colour to reach any each of the cylinders and note the observations.

Conclusion

The rate of diffusion of copper sulphate in water is in the order as given below:

Beaker 3 > Beaker 2 > Beaker 1

Thus, smaller particles undergo diffusion more quickly than bigger particles.

Result

1. When solids such as copper sulphate are brought in contact with liquids such as water, intermingling of substances, i.e., diffusion takes place.
2. The rate of diffusion varies directly with temperature.
3. Small particles undergo diffusion more quickly than bigger particles.
